

# HW1

Shane Drafahl

29 August, 2017

1. Define a DFA, simplified to the best of your abilities, to recognize the language  $L = \{ a^i b^j : (i + j) \bmod 3 = 0 \}$

2. Describe in a short English sentence the language accepted by the following DFA, and give a regular expression for it (hint: the names of the states reflect their meaning). Then, define a 5-state NFA that accepts the same language.

This DFA takes in characters from a alphabet of  $\Sigma = \{1, 0\}$ . From left to right they are concatenated into binary numbers. The string must end with 4 binary numbers that are inclusive values between 0-7 after converting the last 4 binary numbers into decimal values.

Regular expression:  $(0 + 1)^*0(0 + 1)(0 + 1)(0 + 1)$

3. Define a DFA equivalent to the following NFA.
